

A **RESTful API** is an application program interface ([API](#)) that uses [HTTP](#) requests to **GET**, **PUT**, **POST** and **DELETE** data.

A RESTful API -- also referred to as a **RESTful web service** -- is based on representational state transfer ([REST](#)) technology, an architectural style and approach to communications often used in [web services](#) development.

REST technology is generally preferred to the more robust Simple Object Access Protocol ([SOAP](#)) technology because REST leverages less [bandwidth](#), making it more suitable for internet usage. An API for a website is [code](#) that allows two software programs to communicate with each another. The API spells out the proper way for a developer to write a program requesting services from an [operating system](#) or other [application](#).

The REST used by [browsers](#) can be thought of as the language of the [internet](#). With cloud use on the rise, APIs are emerging to expose web services. REST is a logical choice for building APIs that allow users to connect and interact with [cloud services](#). RESTful APIs are used by such sites as [Amazon](#), [Google](#), [LinkedIn](#) and [Twitter](#).

How RESTful APIs work

A RESTful API breaks down a [transaction](#) to create a series of small modules. Each [module](#) addresses a particular underlying part of the transaction. This modularity provides developers with a lot of flexibility, but it can be challenging for developers to design from scratch. Currently, the models provided by [Amazon Simple Storage Service](#), [Cloud Data Management Interface](#) and [OpenStack Swift](#) are the most popular.

A RESTful API explicitly takes advantage of HTTP methodologies defined by the RFC 2616 protocol. They use GET to retrieve a resource; PUT to change the state of or update a resource, which can be an [object](#), [file](#) or [block](#); POST to create that resource; and DELETE to remove it.

With REST, networked components are a resource you request access to -- a [black box](#) whose implementation details are unclear. The presumption is that all calls are stateless; nothing can be retained by the RESTful service between executions.

Because the calls are [stateless](#), REST is useful in cloud applications. Stateless components can be freely redeployed if something fails, and they can [scale](#) to accommodate [load](#) changes. This is because any request can be directed to any instance of a component; there can be nothing saved that has to be remembered by the next transaction. That makes REST preferred for web use, but the RESTful model is also helpful in cloud services because binding to a service through an API is a matter of controlling how the URL is decoded. [Cloud computing](#) and [microservices](#) are almost certain to make RESTful API design the rule in the future.
